Problems and
Prospects

Provide many insights to
the dynamics of Dark
Matter (DM).

Yet also pose many open
questions...

Open Questions

Universality: all DM halos seem to have (up to scaling) the same density profile (NFW)

$$\rho(r) \propto \frac{1}{r(1+r)^2}$$

- What is the exact inner slope (is there a cusp?)
- Physical mechanism? - Accretion? Violent Relaxation?
- What is the dependence on the cosmological model?
- Additionally, Taylor & Navarro (2001) demonstrated

$$f_{\text{poor man}}(r) \stackrel{\text{def}}{=} \frac{\rho(r)}{\sigma^3(r)} \propto r^{-1.875}$$

So phase-space density is interesting! - but how does it come about?

The Vlasov-Poisson
Equation

Our Work

Estimating

$f(\mathbf{x}, \mathbf{v})$ from an

N -body simulation

Results

Problems and

Prospects

Gravity is an attractive long-range force. Therefore every DM particles only feel the **mean-field** gravitational potential and binary collisions are negligible.

$$\dot{\mathbf{x}}(t) = \mathbf{v}(t), \quad \dot{\mathbf{v}}(t) = -\nabla \cdot \Phi(\mathbf{x}).$$

So if we define the *phase-space density function* $f(\mathbf{x}, \mathbf{v})$

$$f(\mathbf{x}, \mathbf{v})d\mathbf{x}d\mathbf{v} = \text{how much mass in } d\mathbf{x}d\mathbf{v}$$

then it changes smoothly over time and we get a continuity equation - the Vlasov-Poisson equation:

$$\frac{d}{dt}f = \partial_t f + \nabla_x f \cdot \mathbf{v} - \nabla_x \Phi \cdot \nabla_v f = 0, \quad \nabla^2 \Phi(\mathbf{x}) = 4\pi^2 G \int d\mathbf{v} f(\mathbf{x}, \mathbf{v})$$

Phase-Space density is therefore the fundamental field in the problem!

Estimating $f(\mathbf{x}, \mathbf{v})$ numerically

Results

Problems and Prospects

In a hi-res simulation there are usually $10^4 \rightarrow 10^6$ particles in a halo. Phase-space density varies over 9 orders of magnitude!

Simple Box counting and other naive approaches do not work!

Our solution: use DTFE (Schaap & van de Weygaert, 2000)

DTFE - Delaunay Tessellation Field Estimator

A. Klypin

Motivation

N -body simulations
The Vlasov-Poisson
Equation

Our Work

Estimating
 $f(\mathbf{x}, \mathbf{v})$ from an
 N -body simulation
Results

Problems and
Prospects

- 1 Estimate f at the location of every atom i :

$$f_i = \frac{7m_i}{\sum_{\alpha} |D_{\alpha}|}$$

- 2 Estimate the average f for each Delaunay cell:

$$f_{\alpha} = \frac{1}{7} \sum_i f_i$$

Global quantities

$$\int \Psi(\mathbf{x}, \mathbf{v}) d\mathbf{x} d\mathbf{v} \rightarrow \sum_{\alpha} \Psi(\mathbf{x}_{\alpha}, \mathbf{v}_{\alpha}) |D_{\alpha}|$$

Technical Difficulties

Consider a typical sample with 10^6 particles in 6D...

- Each particles has about 7,000 Delaunay cells around it
- With 200 neighboring particles
- Totally, there are about 10^9 Delaunay cells in the system.
- If each cell is represented by the indices of its 7 particles then we need a total of

$$7 \times 4 \times 10^9 \text{ bytes} = 28\text{GB}$$

just to store the tessellation.

conclusion

We need a program that caches some of the information to the disk, and possibly makes some of the analysis while finding the Delaunay cells.

Results

Problems and Prospects

- Is a free software (GNU GPL).
- Written in C. Sequential algorithm. Based on a sequential algorithm of Tanemura, Ogawa & Ogita (1983) + improvements due to van de Weygaert (1994) (mainly use of $k - d$ trees).
- The program goes particle by particle, finding all its Delaunay cells. After every K particles, data is cached to/from the disk.
- Once all calculations of a given cell have been done - it is no longer kept.
- Suitable for running on an ordinary PC. For example, 10^6 particles will take about 3 days on a recent laptop (Intel Pentium M 1.7 GHz with 1GB RAM), and will take 7GB disk-space.
- Fairly modular and extendible.

Results - the $v(f)$ function

Phase-space
density

I. Arad, A. Dekel,
A Klypin

Motivation

N -body simulations
The Vlasov-Poisson
Equation

Our Work

Estimating
 $f(\mathbf{x}, \mathbf{v})$ from an
 N -body simulation

Results

Problems and
Prospects

We first looked at the $v(f)$ function:

$$v(f_0) \stackrel{\text{def}}{=} \int d\mathbf{x} d\mathbf{v} \delta[f(\mathbf{x}, \mathbf{v}) - f_0]$$

$v(f_0)df_0$ - The volume occupied by
 $f_0 < f(\mathbf{x}, \mathbf{v}) < f_0 + df_0$

Very well described by a power-law
 $f^{-2.5}$

However, a smooth halo with
 $v(f) \propto f^{-2.5}$ implies $\rho(r) \propto r^{-2}$!

Results

Problems and
Prospects

The problem

There does not seem to be any natural dimensional scaling between velocity and position. Using different units leads to different tessellations

Possible Solutions

- Scale v, x by the mean dispersion in the halo (not optimal).
- Use local metric, by either local dispersion, or some local timescale $T = \mathbf{v} / \nabla \Phi(\mathbf{x})$ - computationally very hard. Is really needed?
- Use a global canonical transformation (\mathbf{x}, \mathbf{v} are actually conjugate)

$$X = \frac{\partial F(V, x)}{\partial V}, \quad v = -\frac{\partial F(V, x)}{\partial x}.$$

Motivation

N -body simulations
The Vlasov-Poisson
Equation

Our Work

Estimating
 $f(\mathbf{x}, \mathbf{v})$ from an
 N -body simulation

Results

Problems and
Prospects

- DTFE is **much** slower than FiEstAS, but gives better results at high densities.
- To be more attractive it needs a smoothing scheme.
- One possibility - hierarchy of smoothing:

$$f_i^{(0)} = \frac{7m_i}{\sum_{\alpha} |D_{\alpha}|} \quad f_{\alpha}^{(0)} = \frac{1}{7} \sum_i f_i^{(0)},$$
$$f_i^{(1)} = \frac{\sum_{\alpha} |D_{\alpha}| f_{\alpha}^{(0)}}{\sum_{\alpha} |D_{\alpha}|} \quad f_{\alpha}^{(1)} = \frac{1}{7} \sum_i f_i^{(0)},$$

- Conserves mass, but produces large biases - Perhaps because of boundary effects.

Structure finder in phase-space

Phase-space density

I. Arad, A. Dekel,

Motivation

N -body simulations
The Vlasov-Poisson
Equation

Our Work

Estimating
 $f(\mathbf{x}, \mathbf{v})$ from an
 N -body simulation
Results

Problems and Prospects

We can use the Delaunay mesh to find substructure in haloes (work in progress by Michael Maciejewski, IAP)

- Find a local maxima of $f(\mathbf{x}, \mathbf{v})$ (all neighboring particles have lower density)
- Look recursively at all its neighbors.
- Process stops below a given density threshold, or some more sophisticated condition.

Advantages

- Fewer free parameters.
- Greater contrast of substructure density in phase-space.
- Ability to detect streams - remnants of merger events.

Results

Problems and Prospects

- Understanding the phase-space structure of dark-matter halos is crucial to understanding the physics behind their structure. Much work remains in this area.
- The DTFE can be used to estimate the phase-space density. However, it is a very expansive process which also involves conceptual difficulties (e.g. position vs. velocity) as well as technical difficulties (e.g. smoothing the fluctuations). It is still not clear that this is the preferred method.
- Substructure in DM halos is much more pronounced in phase-space than in real-space. This gives rise to interesting applications in structure finding.
- The scale invariance in $v(f)$ is due to the distribution of substructure - and not due to the smooth background. The relation $f(r) = \frac{\rho(r)}{\sigma^3(r)} \propto r^{-1.875}$ is still not understood.
