LSS2014 PRESENTATION TOPICS

Dear Cosmic Structure Formation 2014 students,

In this document you find a listing of suggested topics for the final presentation. Mentioned with most topics are "some" literature suggestions. In some cases this concerns an essential key reference which then would advisably be used for the report. In other cases you find a listing of publications that would provide you with a good overview of important papers relating to the subject, and it will be up to you to select the ones you need (in addition of course to other works you find yourself as revelant).

Take care that your presentation is a review of relevant work, not JUST a summary of one or two papers. It should be a critical discussion, and place the topic within the context of ongoing reseach.

Have fun, looking forward to your presentations,

Rien van de Weygaert

Kapteyn Institute,

9700 AV Groningen

1. Evidence for Dark Energy.

- A discussion on the observational evidence for a cosmological constant Lambda or, in a wider context, for the reality of Dark Energy. Is it realistic to measure the real equation of state of the vacuum ?

- *Literature suggestions:*

    Rev. Mod. Phys. 61, 1

2. Baryonic Oscillations

- Baryonic oscillations in the power spectrum of galaxy clustering have recently been detected from the 2dFGRS and SDSS galaxy redshift survey. At the moment various deep redshift surveys are being designed to measure the baryonic oscillations and get a precise measurement of the equation of state of dark energy from this purely geometric and robust method. Give a discussion of the fundamental physics behind the oscillations, on the detection and measurement of the oscillations and on the prospects to study dark energy.

3. The Cosmic Web

- On scales of a few up to more than a hundred Megaparsec displays galaxies delineate a salient and pervasive weblike pattern, the *Cosmic Web* (Bond et al. 1996). Galaxies and mass are arranged into elongated filaments, sheetlike walls and dense compact clusters. These surround large *voids*, enormous regions with sizes in the range of $20-50h^{-1}$ Mpc that are practically devoid of any galaxy, usually roundish in shape and occupying the major share of space in the Universe. Write a review on observational aspects of the cosmic web, along with a discussion of N-body simulations revealing the same weblike structure. Literature is too vast to provide any decent measure of fitting references. Please contact RvdW. A few suggestions ...

4. Voids and the Large Scale Structure

- Voids are a major component of the Megaparsec Universe. With the arrival of the 2dFGRS and SDSS galaxy redshift surveys it is finally possible to obtain a global picture of their characteristics. Review their properties, discuss their role within the formation of large scale structure (both from an observational and theoretical point of view), discuss their sensitivity to cosmological parameters and evaluate what void galaxies can teach about galaxy formation.

5. Hierarchical Clustering and the Excursion Set Formalism

- Structure in the Universe builds up in a hierarchical fashion: the first objects to form are small, larger ones form by the gradual merging of smaller clumps. To see how such structures emerge out of an initially Gaussian density field a sophisticated mathematical formalism has been developed, the socalled *excursion set formalism*. This formalism allows the computation of the resulting mass spectrum of galaxies and clusters, the development of the void distribution, even that of the *Cosmic Web* and the merging history of halos in a hierarchically evolving mass distribution. Discuss the essential ingredients of this elegant formalism, establish the link with diffusion equations, and evaluate its successes and limitations.

6. Cluster Evolution and Intracluster Medium

- Clusters of galaxies are the most massive fully collapsed and virialized objects in the Universe. In fact, they are huge balls of hot $10^7 - 10^8$ K intracluster gas. Describe the evolution of clusters, focussing in particular on that of the hot X-ray emitting gas.

7. Clusters and the Sunyaev-Zel'dovich effect

- The hot intracluster gas in clusters may scatter CMB photons to higher frequencies. The resulting spectrum is no longer blackbody. This effect, the Sunyaev-Zel'dovich effect, may open the way towards mapping all clusters throughout the observable Universe. There are two effects, the thermal and the kinetic SZ effect. Describe the effect, present some recent results and analyze the prospects for future experiments like the Planck satellite.

8. Cosmology and Clusters of Galaxies

- Clusters of galaxies are the most massive fully collapsed and virialized objects in the Universe. The population of clusters and its evolution are sensitive probes of underlying cosmology and of the spectrum of density fluctuations. In particular interesting is the mass spectrum $n(M)$ of clusters of mass M. On the basis of theoretical predictions one can infer its sensitivity to the cosmological mass density Ω_m, on the power spectrum of density fluctuations and in particular its amplitude (expressed in terms of σ_8, the root mean square of density fluctuations within a sphere of radius $8h^{-1}$Mpc). Discuss the theoretical framework of predicted cluster mass spectra (both analytically as well as by means of N-body simulations). In addition, discuss the constraints on cosmological parameters obtained from such studies, in particular on the basis of samples of X-ray clusters. Finally, show how these in combination with CMB experiments yield estimates of in particular Ω_m and Ω_Λ.

10. Cosmic Flows and Redshift Space Distortions

- Due to the matter migration flows accompanying the formation of structure in the Universe, maps of galaxies in redshift space are a combination of their true spatial distribution and systematic distortions resulting from the peculiar velocities of galaxies. Investigate the possible effects, provide an overview on the attempt to theoretically describe this and discuss results on the basis of (recent) galaxy redshift surveys.

11. Weak Lensing by Large Scale Structure

- The finding of cosmic shear induced by the inhomogeneous matter distribution in the Universe has triggered enormous activity in trying to infer cosmological parameters, estimating the cosmic power spectrum and ultimately mapping the dark matter distribution throughout the Universe on the basis of the slight distortions of galaxy images by weak lensing by the cosmic mass distribution. Provide a review of the theoretical predictions, of analysis methods, and achieved results, culminating in the first map of the cosmic dark matter distribution.

12. Power Spectrum Estimation

- The density fluctuation power spectrum $P(k)$ is one of the most essential ingredients for any theory of structure formation: to a large extent it determines the mode, nature and rate of the emergence of galaxies, clusters and all elements of the cosmic foam in the Universe. Trying to determine the power spectrum from the many sources of information on cosmic structure is one of the major activities of cosmological studies. Provide a discussion of the various methods. Concentrate in particular on the machinery that has been developed to extract significant estimates of $P(k)$ from galaxy redshift surveys.

13. Cosmic Microwave Background Radiation: Thermalization and Spectral Distortions

- The cosmic microwave background radiation provides the strongest observational foundation for the standard Hot Big Bang theory. The fact that its electromagnetic spectrum is almost perfectly Blackbody sets severe constraints on 1) the thermalization processes and epoch of the radiation and 2) spectrum distorting processes. While the anisotropies in the CMB provide a wealth of information on the Universe around the epoch of recombination ($z \sim 1089$), the CMB Planck spectrum forms a probe of the Universe out to redshifts $z \sim 10^7$. Investigate in detail the physical processes that lead to the thermalization of the CMB, and discuss the possible observational spectral signatures incurred by distorting energetic processes at $z < 10^7$. Discuss the observational constraints on the various observational signatures.

14. CMB Experiments: Maps, Power Spectra and Cosmological Parameter Estimation

- On the basis of the raw data of CMB temperature measurements across the sky obtained through microwave background experiments (e.g. COBE, Boomerang and WMAP), a data analysis machinery should process this into maps of the MWB sky, of the power spectrum C_l and ultimately significant estimates of cosmological parameters. Describe the various steps of this process, in this concentrating particularly on the mapmaking procedures and the estimation of the power spectrum. The latter involves a discussion on the statistical and numerical methods developed to obtain optimal estimates of C_l, including a description of the CMBFAST package for fast theoretical power spectrum computation.

15. Cosmic Microwave Background Anisotropies: Characteristic Angular Scales

- Four characteristic angular scales are imprinted on the spectrum of Microwave Background Anisotropies. These are the scale corresponding to the radiation-matter equality ℓ_{eq}, the scale ℓ_A corresponding to the cosmic sound horizon at the epoch of decoupling, the diffusion scale ℓ_D due to (Silk) scattering diffusion and finally the scale $\ell_{K\Lambda}$ at which either the curvature or the cosmic constant takes over from matter as dominant factor behind the expansion of the Universe. Provide a discussion how the various relevant physical processes (Sachs-Wolfe, acoustic oscillations, Silk diffusion damping, Integrated Sachs-Wolfe, etc.) are relating to these characteristic scales and how this leads to differences in angular power spectrum of cosmic microwave background fluctuations.

16. Cosmic Microwave Background Polarization

- In addition to CMB temperature anisotropies, polarization of the Microwave Background Signal contains a wealth of information on processes in the early Universe (inflationary gravitational waves and primordial velocity field), on the cosmic matter distribution (weak gravitational lensing of the CMB signal) on secondary post-recombination scattering processes. Of the latter in particular that induced by gas ionized by the first generation of stars and galaxies at and around the epoch of reionization provides an exciting new avenue of research, in particular since the polarization detection by DASI and WMAP. Investigate the physical nature of the various sources of CMB polarization, describe their (expected) imprint (E and B modes) and signature (EE autocorrelation, TE cross-correlation), and the way they can and are exploited to infer important cosmological information.

17. The First Stars

- One of the most important transitions in the state of the Universe is the epoch at which the first stars and galaxies arise out of the gradually unfolding matter distribution. The first generation of stars, Population III stars, are extremely metal poor and will have differed considerably from the stars we know of nowadays. Write an review on the formation and evolution of these stars and investigate the enrichment products following their explosion as supernova.

18. Epoch of Reionization

- One of the most important transitions in the state of the Universe is the epoch at which the first stars and galaxies arise out of the gradually unfolding matter distribution, set ablaze the surrounding gas and very soon thereafter reionizes the hydrogen gas throughout the Universe. The *Epoch of Reionization* is one of the most vigorous and active in today's cosmology, with instruments like LOFAR due to play a seminal role. Discuss in the report the processes and stages in which the reionization of the hydrogen gas proceeds, illustrate this with available computer simulations and assess the shortcomings of the present calculations along with the prospects for detection and possibly mapping of the signal.

19. Inflationary Universe and the Origin of Fluctuations

- The primordial fluctuations out of which structure in the Universe has arisen originated in the inflationary epoch shortly after the Big Bang. Give a review on its basic principles, on the mechanism to generate the fluctuations and the tests of the inflationary scenario via the measurement of the temperature and polarization fluctuations in the cosmic microwave background.
